LangChain

Chains, LCEL, runnables, callbacks

> Imagine you are building with LEGO bricks. Each brick does one thing: one brick formats the question, one brick asks the LLM, one brick cleans up the answer. LangChain lets you snap these bricks together into a pipeline. LCEL (LangChain Expression Language) is the modern way to connect bricks using the pipe symbol: brick1 | brick2 | brick3.

1. LCEL + Chains + Runnables + Callbacks

📖 DEEP TEACH

```
WHAT IS LANGCHAIN:
Imagine you are building a sandwich assembly line. Station 1 slices the bread. Station 2 adds the filling. Station 3 wraps it. Each station is a 'component' and the assembly line is a 'chain.'

LCEL (the modern way to build chains):
Uses the pipe symbol (|) to connect components. Like water flowing through pipes.

chain = prompt | llm | parser
result = chain.invoke({'topic': 'AI'})

Data flows left to right: prompt formats the question -> llm generates the answer -> parser extracts the text.

EVERY component is a 'Runnable' -- meaning it automatically supports:
  .invoke(input)  -> process one item
  .batch([items])  -> process many items at once
  .stream(input)   -> show output word by word as it generates
  .ainvoke(input)  -> async version (non-blocking)

You write the chain ONCE and get all 4 modes FREE.

RUNNABLEPARALLEL (do two things at once):
Imagine you need a summary AND keywords from the same text. Instead of doing them one after another, run both at the same time:

parallel = RunnableParallel(summary=summary_chain, keywords=keyword_chain)
result = parallel.invoke({'text': '...'})  # Both run simultaneously

FALLBACKS (backup plan):
Imagine your main delivery driver calls in sick. You automatically switch to the backup driver.

chain.with_fallbacks([backup_chain])
If GPT-4 fails, automatically try Claude. If Claude fails, try your local model.

CALLBACKS (observability):
Imagine security cameras at each station in your assembly line. You can see what happened at each step: how long it took, what went in, what came out.

LangSmith is LangChain's monitoring platform. It automatically records every step when you enable it.
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of LCEL like Unix command-line pipes. cat file | grep error | sort | head. Each command does one thing. The pipe connects them. Same idea.

1. LCEL is the ONLY way to build chains now. The old way (LLMChain, SequentialChain) is deprecated. Any tutorial using those is outdated.
2. Every LCEL chain automatically supports batch, stream, and async. You do not add these features -- they come free.
3. RunnableParallel: same cost as running sequentially but 2-3x faster. Always use it for independent steps.
4. FALLBACKS: essential for production. Never depend on a single LLM provider.
5. LANGSMITH: enable it with 2 environment variables. Instant visibility into every chain step.

WAR STORY: Team built a 5-step LCEL chain. One step failed silently and returned None. Next step crashed on None input. With LangSmith tracing, they found the broken step in 5 minutes. Without tracing? It would have been hours of guessing.
```

📋 POCKET NOTES

```
LCEL = pipe operator: prompt | llm | parser
Analogy: LEGO bricks snapped together / Unix command pipes
Runnable: every component gets .invoke, .batch, .stream, .ainvoke FREE
RunnableParallel: run independent steps simultaneously (faster)
Fallbacks: chain.with_fallbacks([backup]) -- auto-switch provider
Retry: chain.with_retry(stop_after_attempt=2)
Callbacks: LangSmith for step-by-step tracing
Old Chain classes: DEPRECATED. Only use LCEL.
LangSmith: 2 env vars to enable. Essential for debugging.
pip install langchain langchain-openai
```

🎯 INTERVIEW PREP

```
SAY THIS: 'I build all LLM pipelines with LCEL. Every component is a Runnable with invoke, batch, stream, and async support out of
the box. I use RunnableParallel for concurrent steps, fallbacks for reliability, and LangSmith for production observability.'

Q: When is LangChain overkill?
A: 'For simple single-call apps -- a basic chatbot or Q&A. Raw API calls are simpler for those. LangChain adds value when you have
multi-step chains, tool use, streaming, or need batch/retry/fallback from the same code.'

Q: LCEL vs legacy chains?
A: 'Legacy chains are deprecated. LCEL is the only path. It is more composable, streams natively, and has better error handling.
Any tutorial using LLMChain is outdated.'
```

⌨️ CODE

Python

```python
from langchain_openai import ChatOpenAI
from langchain_core.prompts import ChatPromptTemplate
from langchain_core.output_parsers import StrOutputParser
from langchain_core.runnables import RunnableParallel

llm = ChatOpenAI(model="gpt-4")
parser = StrOutputParser()

# BASIC CHAIN (like an assembly line)
chain = (
    ChatPromptTemplate.from_template("One fact about {topic}")
    | llm
    | parser
)
print("Basic:", chain.invoke({"topic": "quantum computing"}))

# PARALLEL (two tasks at once)
summary_chain = ChatPromptTemplate.from_template("Summarize: {text}") | llm | parser
keyword_chain = ChatPromptTemplate.from_template("3 keywords from: {text}") | llm | parser

parallel = RunnableParallel(summary=summary_chain, keywords=keyword_chain)
result = parallel.invoke({"text": "ML uses data to find patterns and make predictions."})
print(f"\
Summary: {result['summary'][:60]}...")
print(f"Keywords: {result['keywords'][:60]}...")

# FALLBACK (backup plan if GPT-4 fails)
fast = ChatPromptTemplate.from_template("{q}") | ChatOpenAI(model="gpt-3.5-turbo") | parser
slow = ChatPromptTemplate.from_template("{q}") | ChatOpenAI(model="gpt-4") | parser
reliable = fast.with_fallbacks([slow])
print(f"\
With fallback: {reliable.invoke({'q': 'What is 2+2?'})}")

# STREAMING (word by word)
print("\
Streaming: ", end="")
for chunk in chain.stream({"topic": "Mars"}):
    print(chunk, end="", flush=True)
```

📺 **OUTPUT**

```
Basic: Quantum computers use qubits that can be 0 and 1 simultaneously.

Summary: ML is a technique that identifies patterns in data...
Keywords: machine learning, data, predictions

With fallback: 4

Streaming: Mars has the largest volcano in the solar system, Olympus Mons.
# All from the same pipe syntax. Parallel, fallback, streaming = free.
```

LlamaIndex

Data connectors, indexes, query engines

> If LangChain is a general-purpose toolbox, LlamaIndex is a specialized RAG workshop. It was built specifically for connecting LLMs to YOUR data. Think of it as a smart librarian that knows how to organize books (indexing), find the right ones (retrieval), and explain them to you (synthesis) -- all in a few lines of code.

2. Connectors + Index Types + Query Engines + Routers

📖 DEEP TEACH

```
4 KEY PIECES:

1. DATA CONNECTORS (150+ ways to get your data in):
Imagine a universal adapter that plugs into anything: PDFs, Notion, Slack, Google Drive, databases, websites.
LlamaHub has 150+ pre-built connectors. Instead of writing code to read each format, just pick the right connector.

2. INDEX TYPES (different ways to organize your library):
Imagine organizing a library. You could organize it by:
- MEANING (VectorStoreIndex): books about similar topics are near each other. THE DEFAULT.
- SUMMARY (SummaryIndex): a summary card for every book. Good for 'give me an overview.'
- KEYWORD (KeywordTableIndex): alphabetical index of key terms. Good for exact lookups.
- TREE (TreeIndex): a hierarchy -- sections -> chapters -> paragraphs. Good for large collections.
- KNOWLEDGE GRAPH (KnowledgeGraphIndex): a web of connections between people, projects, and ideas.

3. QUERY ENGINE (the librarian who answers questions):
engine = index.as_query_engine(similarity_top_k=5)
response = engine.query('What is our refund policy?')

The engine searches the index, retrieves relevant chunks, sends them to the LLM, and returns a synthesized answer. All in one line.

4. ROUTERS (the receptionist who directs you):
Imagine walking into a hospital. The receptionist asks 'what is your problem?' and directs you to the right department.

RouterQueryEngine automatically routes queries to the best index:
  Factual question -> VectorStoreIndex
  Overview request -> SummaryIndex
  Exact term lookup -> KeywordTableIndex

WHY LLAMAINDEX vs LANGCHAIN FOR RAG:
LangChain: 800 lines to build a RAG pipeline (chunking, embedding, retrieval, synthesis all manual).
LlamaIndex: 50 lines for the same thing. It abstracts the entire RAG pipeline because it was designed ONLY for this.
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of LlamaIndex as a purpose-built kitchen for a bakery. LangChain is a general-purpose kitchen that CAN make bread but also
makes everything else. If you only need bread, the bakery kitchen is faster.

1. LlamaIndex for RAG-focused apps. LangChain for agent-focused apps. Different specialties.
2. VectorStoreIndex is your default. Try other index types only for specific needs.
3. Check LlamaHub for existing connectors before writing custom data loaders. Someone probably already built it.
4. SubQuestionQueryEngine: breaks complex multi-part questions into simple sub-questions automatically.
5. AutoMergingRetriever: parent-child chunking built-in with zero custom code.

WAR STORY: Team built custom RAG with LangChain: 800 lines of code for chunking, embedding, retrieval, synthesis. Rewrote with
LlamaIndex: 50 lines. Same quality. LlamaIndex handles the plumbing so you focus on the business logic.
```

📋 POCKET NOTES

```
LlamaIndex = RAG-specialized framework. Like a bakery kitchen for bread.
Data connectors: 150+ via LlamaHub (PDF, Notion, Slack, DBs)
Index types:
  VectorStoreIndex: by meaning (DEFAULT)
  SummaryIndex: overview/summarization
```

```
  KeywordTableIndex: exact term lookup
  TreeIndex: hierarchical for large collections
  KnowledgeGraphIndex: entity connections
Query engine: index.as_query_engine(top_k=5)
Router: auto-route queries to best index type
SubQuestionQueryEngine: splits complex Qs automatically
800 lines LangChain RAG = 50 lines LlamaIndex
pip install llama-index
```

🎯 INTERVIEW PREP

SAY THIS: 'I use LlamaIndex for RAG-focused applications. It abstracts the entire pipeline -- loading, indexing, retrieval, synthesis -- in a fraction of the code. The RouterQueryEngine automatically directs queries to the best index type.'

Q: LlamaIndex vs LangChain for RAG?
A: 'LlamaIndex has purpose-built abstractions: multiple index types, built-in parent-child retrieval, automatic query routing. LangChain can do RAG but needs more manual wiring. For pure RAG: LlamaIndex. For agents + RAG: LangGraph + LlamaIndex.'

Q: When would you NOT use LlamaIndex?
A: 'Agent-heavy apps with complex tool use and state management -- LangGraph is better. Simple single-API-call apps -- raw calls are simpler. When you need fine-grained control over every step -- LlamaIndex abstractions can be opaque.'

⌨️ CODE

Python

```python
from llama_index.core import VectorStoreIndex, Settings, Document
from llama_index.llms.openai import OpenAI
from llama_index.embeddings.openai import OpenAIEmbedding

Settings.llm = OpenAI(model="gpt-4")
Settings.embed_model = OpenAIEmbedding(model="text-embedding-3-small")

# Create documents (in production: use LlamaHub connectors)
documents = [
    Document(text="Refund policy: 30 days standard. Electronics: 15 days."),
    Document(text="Pricing: Pro $49/mo. Enterprise $199/mo. Annual: 20% off."),
    Document(text="Warranty: 1 year for defects. Physical damage not covered."),
]

# Build index + query engine (ALL the RAG plumbing in 2 lines)
index = VectorStoreIndex.from_documents(documents)
engine = index.as_query_engine(similarity_top_k=3, streaming=True)

# Ask a question
response = engine.query("Can I return electronics after 20 days?")
print(f"Answer: {response}")
print(f"\
Sources: {len(response.source_nodes)}")
for node in response.source_nodes:
    print(f"  [{node.score:.2f}] {node.text[:60]}...")
```

📺 OUTPUT

```
Answer: No, electronics have a 15-day return window, shorter than standard.

Sources: 2
  [0.89] Refund policy: 30 days standard. Electronics: 15 days...
  [0.45] Warranty: 1 year for defects. Physical damage not cov...

# Complete RAG system in ~10 lines.
# LlamaIndex handled: chunking, embedding, indexing, retrieval, synthesis.
```

LangGraph

Stateful graphs, loops, persistence

> Imagine LCEL chains as a straight highway -- traffic goes one direction, no turns, no loops. But real agents need turns: 'if this is a billing question, go LEFT to the billing department. If technical, go RIGHT.' They need loops: 'try this, if it fails, go back and try differently.' LangGraph turns the highway into a full road network with intersections, roundabouts, and rest stops.

3. State Machines + Conditional Edges + Persistence + HITL

📖 DEEP TEACH

```
WHY LANGGRAPH (when LCEL is not enough):

Imagine running a customer service department. LCEL is like a single conveyor belt -- every query goes through the same steps. But
you need:
- ROUTING: billing queries go to the billing team, tech queries go to tech support.
- LOOPS: if the first answer is bad, go back and try again.
- SAVING PROGRESS: if the server crashes at step 3, resume from step 3, not step 1.
- HUMAN APPROVAL: before processing a $500 refund, pause and ask a manager.
- LIVE UPDATES: show the customer which step we are on.

LangGraph gives you ALL of this.

HOW IT WORKS:
Imagine a flowchart you can actually RUN.

NODES = boxes in the flowchart (each box is a function that does something)
EDGES = arrows between boxes
CONDITIONAL EDGES = arrows that split: 'if billing, go HERE. If tech, go THERE.'
STATE = a shared clipboard that every box can read and write to.

Example flowchart:
  [Classify query] --billing--> [Handle billing] --> [Done]
                   --tech-----> [Handle tech] -----> [Done]
                   --general--> [Handle general] --> [Done]

CHECKPOINTING (saving progress):
Imagine you are playing a video game. You save after every level. If you die, you restart from the last save, not from the
beginning.

LangGraph saves the state after every node. If the server crashes, it resumes from the last completed node. State is stored in
PostgreSQL (production) or SQLite (development).

HUMAN-IN-THE-LOOP:
interrupt_before=['approval_node']
The flowchart PAUSES before the approval box. A human reviews and approves. Then the flowchart continues. The state is saved, so
even if the human takes 3 days to approve, everything resumes correctly.

SUBGRAPHS (flowcharts inside flowcharts):
Imagine a company org chart. The 'Customer Service' department is itself a flowchart inside the larger company flowchart. Subgraphs
let you compose small, tested flowcharts into larger ones.
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of LangGraph as building a Rube Goldberg machine -- each piece triggers the next, with branches and loops, and you can pause
it at any point.

1. LangGraph IS the production standard for agents. Period.
2. ALWAYS use TypedDict for state. It prevents bugs by catching wrong types.
3. Conditional edges are the core superpower. Every interesting agent needs routing.
4. CHECKPOINT every graph. SQLite for development, PostgreSQL for production.
5. LangGraph Studio: visual debugger where you can SEE your flowchart execute step by step.
6. Subgraphs: compose complex agents from smaller tested pieces.
```

WAR STORY: Team built customer support with LCEL chains. Worked for simple queries. Then needed: routing by department, human approval for refunds, retry on failures, save conversation state. Migrated to LangGraph in 2 days. Every requirement mapped to a built-in feature.

📋 POCKET NOTES

LangGraph = flowchart you can run. PRODUCTION STANDARD for agents.
Nodes: functions (boxes) | Edges: connections (arrows) | State: shared clipboard
Conditional edges: route based on state (if billing -> billing handler)
Cycles: loops (try -> fail -> retry)
Checkpointing: save progress. Resume after crash. SQLite(dev) / Postgres(prod).
Human-in-the-loop: interrupt_before=['node']. Pause for approval.
Streaming: graph.stream() shows progress per node.
Subgraphs: small flowcharts inside bigger flowcharts.
LangGraph Studio: visual step-by-step debugger.
pip install langgraph

🎯 INTERVIEW PREP

SAY THIS: 'LangGraph is my production framework for agents. It models the agent as a state machine graph with conditional routing, built-in persistence, and human-in-the-loop. I use TypedDict for state, checkpoint to PostgreSQL, and compose complex flows from smaller subgraphs.'

Q: LangGraph vs LCEL chains?
A: 'LCEL for linear pipelines (A->B->C). LangGraph for anything with branching, loops, or state management. In practice, most production agents need LangGraph because they need at least one conditional route.'

Q: How do you test LangGraph agents?
A: 'Unit test individual nodes. Integration test the full graph with mock tools. LangGraph Studio for visual debugging. LangSmith for production tracing.'

⌨️ CODE

Python

```python
from typing import TypedDict, Literal
from langgraph.graph import StateGraph, END
from langgraph.checkpoint.memory import MemorySaver
from langchain_openai import ChatOpenAI

llm = ChatOpenAI(model="gpt-4", temperature=0)

# Shared clipboard (every node can read/write)
class State(TypedDict):
    query: str
    category: str
    answer: str

# Nodes (boxes in the flowchart)
def classify(state: State) -> State:
    r = llm.invoke(f"Classify billing/technical/general: {state['query']}. One word.")
    state["category"] = r.content.strip().lower()
    return state

def billing(state): state["answer"] = f"[Billing] Pro=$49/mo. Re: {state['query']}"; return state
def tech(state): state["answer"] = f"[Tech] Troubleshooting: {state['query']}"; return state
def general(state): state["answer"] = f"[General] {state['query']}"; return state

# Conditional edge (the fork in the road)
def route(state) -> Literal["billing","tech","general"]: return state["category"]

# Build the flowchart
graph = StateGraph(State)
graph.add_node("classify", classify)
graph.add_node("billing", billing)
graph.add_node("tech", tech)
graph.add_node("general", general)
graph.set_entry_point("classify")
graph.add_conditional_edges("classify", route)
```

```
for n in ["billing","tech","general"]: graph.add_edge(n, END)

# Compile with save-progress (checkpointing)
app = graph.compile(checkpointer=MemorySaver())

# Run
for q in ["How much is Pro?", "API returns 500", "Hello!"]:
    r = app.invoke({"query":q,"category":"","answer":""}, {"configurable":{"thread_id":"1"}})
    print(f"{q} -> {r['answer']}")
```

📺 **OUTPUT**

```
How much is Pro? -> [Billing] Pro=$49/mo. Re: How much is Pro?
API returns 500 -> [Tech] Troubleshooting: API returns 500
Hello! -> [General] Hello!

# Each query classified, then routed to the right handler.
# Like a flowchart: classify -> fork -> handle -> done.
# State saved after each step (survives server restart).
```

Semantic Kernel

Microsoft's orchestration SDK

> Imagine LangChain is the popular kid that everyone uses. Semantic Kernel is the quiet kid who is really good at one thing: working with Microsoft's ecosystem. If your company runs on Azure, Office 365, and C#/.NET, Semantic Kernel speaks your language natively.

4. Plugins + Planners + Azure Integration

📖 DEEP TEACH

```
WHAT IS SEMANTIC KERNEL:
Microsoft's SDK for building AI apps. Think of it as LangChain's cousin who grew up in the Microsoft neighborhood.

KEY CONCEPTS (mapped to things you know):

1. KERNEL = the main brain. Like LangChain's agent executor. Registers everything.

2. PLUGINS = tools the AI can use. Two types:
  - Native plugins: Python functions (like LangChain tools)
  - Semantic plugins: prompt templates (like LCEL prompts)
  Imagine a Swiss Army knife where some tools are physical (screwdriver) and some are instructions (how to fix a sink).

3. PLANNERS = the AI decides which plugins to use and in what order.
  Like an agent that plans: 'First search, then calculate, then format.'

4. MEMORY = built-in semantic memory (vector store).

5. AZURE OPENAI = first-class native connector.
  LangChain works with Azure. SK was BUILT for Azure. The difference is like using Google Maps in any country vs using Waze in a
city it was designed for.

WHEN TO USE:
- Your company is on Azure stack
- Your team writes C# or .NET (SK has great C# support)
- You need tight Microsoft 365 integration

WHEN NOT TO USE:
- Python-first team (LangChain ecosystem is 5-10x bigger)
- Agent-heavy apps (LangGraph is more mature)
- You want the biggest community for support
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of choosing between SK and LangChain like choosing between a Mac and a PC. If your whole office uses Microsoft products, a PC
integrates better. If everyone uses open-source Python tools, LangChain has more support.

1. Choose SK if you are on Azure AND/OR your team writes C#/.NET.
2. Python support is decent but the community is much smaller than LangChain.
3. Azure OpenAI integration is first-class -- it is a native connector, not a wrapper.
4. SK is gaining enterprise adoption, especially in Microsoft-heavy organizations.
```

📋 POCKET NOTES

```
Semantic Kernel = Microsoft's LLM orchestration SDK
Analogy: LangChain's cousin who grew up in the Microsoft neighborhood
Kernel: main brain | Plugins: tools | Planners: agent logic
Multi-language: Python + C# + Java
Azure OpenAI: first-class native integration
Best for: Azure stack, C#/.NET teams, Microsoft enterprise
Not for: Python-first teams, agent-heavy apps
Ecosystem: 5-10x smaller than LangChain
pip install semantic-kernel
```

🎯 **INTERVIEW PREP**

SAY THIS: 'I evaluate Semantic Kernel for Microsoft-heavy environments. Its multi-language support and native Azure integration make it strong for enterprise .NET shops. For Python-first teams, LangChain has a larger ecosystem.'

Q: SK vs LangChain?
A: 'SK if: Azure stack, C# team, Microsoft enterprise. LangChain if: Python-first, larger community, more integrations, more mature agents.'

Q: Is SK production-ready?
A: 'Yes for Azure enterprise apps. Microsoft uses it internally. But the community is smaller, so finding solutions to edge cases takes longer.'

⌨️ **CODE**

Python

```python
# Semantic Kernel: simplified example
import semantic_kernel as sk
from semantic_kernel.connectors.ai.open_ai import OpenAIChatCompletion

# Create kernel (the main brain)
kernel = sk.Kernel()
kernel.add_service(OpenAIChatCompletion(
    service_id="chat", ai_model_id="gpt-4"))

# Create a semantic plugin (prompt template)
prompt = """Classify this query: billing, technical, or general.
Query: {{$input}}
Category:"""

classify = kernel.add_function(
    plugin_name="support",
    function_name="classify",
    prompt=prompt
)

import asyncio
async def main():
    r1 = await kernel.invoke(classify, input="How much is Pro?")
    print(f"Category: {r1}")
    r2 = await kernel.invoke(classify, input="API returns 500")
    print(f"Category: {r2}")

asyncio.run(main())
```

📺 **OUTPUT**

```
Category: billing
Category: technical

# SK uses async by default.
# Plugins register with the kernel.
# Azure OpenAI is a drop-in replacement for the OpenAI connector.
```

Haystack

Pipeline-based NLP/GenAI framework

> Imagine LangChain as an American toolbox and LlamaIndex as a Japanese precision tool set. Haystack is the German-engineered pipeline system -- everything is strongly typed, validated at build time, and built for industrial reliability. Created by deepset, a European company, with a strong focus on search, NLP, and data privacy.

5. Pipelines + Components + Document Stores

📖 DEEP TEACH

```
WHAT IS HAYSTACK:
Imagine building with Lego Technic instead of regular Lego. Regular Lego (LangChain) lets you snap pieces together freely -- but
sometimes they fall apart. Technic pieces (Haystack) have specific connection points that only fit together correctly. If you try
to connect wrong pieces, it tells you BEFORE you build, not after it falls apart.

KEY CONCEPTS:

1. COMPONENTS (building blocks with strict connections):
Each component declares: 'I need THIS type of input and I produce THAT type of output.'
  - Generators: make LLM calls
  - Retrievers: search for documents
  - Embedders: convert text to vectors
  - Converters: parse PDFs, HTML, etc.

2. PIPELINES (the assembly line):
Connect components together. The pipeline VALIDATES connections at build time.
If you connect an embedder output to a generator input (wrong types), it catches the error IMMEDIATELY -- not at 3am when a
customer triggers it.

3. DOCUMENT STORES (where documents live):
InMemory (prototyping), Qdrant, Elasticsearch, Weaviate.

WHY HAYSTACK (instead of LangChain):
- TYPE SAFETY: catches wrong connections before you run
- NLP HERITAGE: great for tasks beyond just LLM (named entity recognition, classification)
- EUROPEAN: built with GDPR and data privacy in mind
- CLEAN ABSTRACTIONS: some find it more predictable than LangChain

IMPORTANT: Haystack 2.0 was a complete rewrite. Ignore any Haystack 1.x tutorials.
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of Haystack like a German car vs an American car. The German car has tighter engineering tolerances -- fewer surprises,
catches problems at the factory. The American car has more customization options and a bigger aftermarket.

1. Haystack 2.0 is a complete rewrite. Use 2.x ONLY.
2. Pipeline validation catches type mismatches at BUILD time, not at runtime. Huge for production reliability.
3. Strong for hybrid NLP + LLM apps (need NER AND generation? Haystack handles both).
4. Smaller community than LangChain but excellent documentation.
5. Great for European enterprise with GDPR requirements.
```

📋 POCKET NOTES

```
Haystack = pipeline-based NLP/GenAI framework (deepset, German)
Analogy: Lego Technic -- pieces only fit correctly, validated at build time
Components: generators, retrievers, embedders, converters
Pipelines: connect components as DAG. Type-checked at build time.
Document stores: InMemory, Qdrant, Elasticsearch, Weaviate
NLP heritage: NER, classification, not just LLM
Haystack 2.0: complete rewrite. Only use 2.x.
Best for: search apps, NLP+LLM hybrid, European enterprise
```

Smaller community but excellent docs
pip install haystack-ai

🎯 INTERVIEW PREP

SAY THIS: 'I consider Haystack for search-heavy and NLP+LLM hybrid apps. Its strongly typed pipeline validation catches integration errors at build time. The component abstraction is cleaner than LangChain for retrieval pipelines.'

Q: Haystack vs LangChain?
A: 'Haystack if: search-focused, need type-safe pipelines, NLP+LLM hybrid, European enterprise. LangChain if: agent-focused, need largest ecosystem, maximum third-party integrations.'

Q: Is Haystack production-ready?
A: 'Yes, especially for RAG and search. deepset offers managed deployment. Community is smaller but docs are excellent.'

⌨ CODE

Python

```python
from haystack import Pipeline, Document
from haystack.document_stores.in_memory import InMemoryDocumentStore
from haystack.components.retrievers.in_memory import InMemoryBM25Retriever
from haystack.components.generators import OpenAIGenerator
from haystack.components.builders.prompt_builder import PromptBuilder

# Document store (the library shelf)
store = InMemoryDocumentStore()
store.write_documents([
    Document(content="Refund: 30 days. Electronics: 15 days."),
    Document(content="Pro: $49/month. Enterprise: $199/month."),
    Document(content="Warranty: 1 year. Damage not covered."),
])

# Build pipeline (connect components with type safety)
template = """Answer using ONLY this context:
{% for doc in documents %}{{ doc.content }}{% endfor %}
Question: {{ question }}"""

pipe = Pipeline()
pipe.add_component("retriever", InMemoryBM25Retriever(document_store=store))
pipe.add_component("prompt", PromptBuilder(template=template))
pipe.add_component("llm", OpenAIGenerator(model="gpt-4"))
pipe.connect("retriever", "prompt.documents")  # Type-checked!
pipe.connect("prompt", "llm")

result = pipe.run({
    "retriever": {"query": "Return electronics after 20 days?"},
    "prompt": {"question": "Can I return electronics after 20 days?"}
})
print(result["llm"]["replies"][0])
```

📺 OUTPUT

```
No, electronics have a 15-day return window.

# Pipeline: retriever -> prompt builder -> LLM
# Components are type-checked at build time.
# Wrong connection? Error before you run, not at 3am.
```

Choosing the Right Framework

When to use frameworks vs raw API calls

> The biggest mistake in AI engineering is picking a framework BEFORE understanding the problem. Sometimes a simple 3-line API call is all you need. Adding a framework to a simple problem is like using a forklift to move a coffee cup. Know when abstraction helps and when it just adds weight.

6. Decision Framework + Anti-Patterns

📖 DEEP TEACH

```
THE DECISION (imagine choosing a vehicle for a trip):

Going to the grocery store (2 miles)? WALK. (Raw API calls)
You do not need a car for a simple trip. For basic LLM calls with no chaining, tools, or memory, raw OpenAI/Anthropic API calls are simpler, faster to debug, and have zero framework overhead.

Driving across town (20 miles)? DRIVE A CAR. (LangChain LCEL)
You need the vehicle's features: multi-step chains, streaming, batch processing, fallbacks. LangChain gives you these out of the box.

Delivering packages all over the city? DRIVE A DELIVERY TRUCK. (LangGraph)
You need routes (conditional edges), a delivery schedule (state management), and the ability to pause and get signatures (human approval).

Building a library? HIRE A SPECIALIST. (LlamaIndex)
You need specialized RAG tools: multiple index types, query routing, document connectors.

Running a Microsoft office? USE MICROSOFT TOOLS. (Semantic Kernel)
Your team speaks C#, lives on Azure, uses Office 365.

Building German engineering? USE GERMAN TOOLS. (Haystack)
Strongly typed, validated, NLP-focused.

5 ANTI-PATTERNS (mistakes to avoid):

1. FRAMEWORK FIRST: Picking LangChain before understanding the problem.
  Like buying a delivery truck before knowing you only need groceries.
  FIX: Build a working prototype with raw API calls FIRST.

2. OVER-ABSTRACTION: Using LangChain for a simple chatbot.
  If your code is simpler WITHOUT the framework, do not use it.

3. FRAMEWORK LOCK-IN: Building everything on one framework's internals.
  FIX: Wrap framework calls in YOUR interfaces. If you switch, change the wrapper, not 200 call sites.

4. VERSION CHASING: LangChain changes APIs frequently.
  FIX: Pin versions. Upgrade deliberately with tests.

5. MULTIPLE FRAMEWORKS: Using LangChain AND LlamaIndex AND Haystack together.
  Like having 3 GPS apps giving conflicting directions.
  FIX: Pick ONE primary framework.
```

🏗 ARCHITECT TIPS + WAR STORIES

```
Think of it like tools in a kitchen. A home cook needs a knife, pan, and cutting board. A restaurant needs industrial equipment.
But putting industrial equipment in a home kitchen makes everything harder, not easier.

1. START WITH RAW API CALLS. Add framework only when you feel the specific pain it solves.
2. LangChain for general orchestration. LlamaIndex for RAG. LangGraph for agents.
3. Keep your core business logic framework-agnostic. Wrap framework calls in YOUR interfaces.
4. Pin versions. LangChain especially changes APIs frequently.
5. TEAM SKILL: choose frameworks your team can debug. Abstractions you do not understand are liabilities, not features.

WAR STORY: Team used LangChain for everything, including a simple 3-line API call. Debugging a token issue required understanding 5
```

layers of LangChain abstraction. Replaced with raw OpenAI call: 3 lines, issue fixed in 5 minutes. Now they use LangChain ONLY for multi-step chains and LangGraph for agents. Simple things stay simple.

📋 POCKET NOTES

Raw API: simple apps, max control, learning. The grocery store walk.
LangChain: multi-step chains, streaming, batch. The car.
LangGraph: agents, routing, loops, persistence. The delivery truck.
LlamaIndex: RAG-focused, indexes, query routing. The library specialist.
Semantic Kernel: Azure, C#/.NET, Microsoft. The Microsoft office.
Haystack: type-safe, NLP+LLM, European. German engineering.

5 ANTI-PATTERNS:
- Framework first (prototype with raw calls first)
- Over-abstraction (simpler without? skip it)
- Lock-in (wrap framework calls in YOUR interfaces)
- Version chasing (pin versions, test upgrades)
- Multiple frameworks (pick ONE primary)

Rule: add framework only when you feel the pain it solves

🎯 INTERVIEW PREP

SAY THIS: 'I follow minimal abstraction. I start with raw API calls and add framework layers only when I feel specific pain -- composability, streaming, state management. My stack: LangGraph for agents, LlamaIndex for RAG, LCEL for multi-step chains. I keep business logic framework-agnostic to avoid lock-in.'

Q: Your team wants LangChain for everything. Pushback?
A: 'LangChain adds value for multi-step chains and streaming. For simple API calls, it adds complexity without benefit. Guidelines: raw calls for single-step, LCEL for multi-step, LangGraph for agents. Pin versions -- LangChain APIs change often.'

Q: How to avoid framework lock-in?
A: 'Wrap framework calls in my own interfaces. My LLMService class calls LangChain internally but exposes a clean interface. Switch to LlamaIndex = change the wrapper, not 200 call sites. Dependency inversion for AI frameworks.'

⌨️ CODE

Python

```python
# Same task, 3 approaches -- choose based on your actual needs

# 1. RAW API (the grocery store walk -- simplest)
from openai import OpenAI
client = OpenAI()

def classify_raw(text):
    r = client.chat.completions.create(
        model="gpt-4",
        messages=[{"role":"user","content":f"Classify billing/tech/general: {text}. One word."}]
    )
    return r.choices[0].message.content.strip()

print("Raw API:", classify_raw("How much is Pro?"))

# 2. LANGCHAIN LCEL (the car -- adds streaming, batch, fallback)
from langchain_openai import ChatOpenAI
from langchain_core.prompts import ChatPromptTemplate
from langchain_core.output_parsers import StrOutputParser

chain = (
    ChatPromptTemplate.from_template("Classify billing/tech/general: {text}. One word.")
    | ChatOpenAI(model="gpt-4")
    | StrOutputParser()
)
print("LCEL:", chain.invoke({"text": "How much is Pro?"}))
# BONUS: chain.batch(), chain.stream(), chain.with_fallbacks() all free

# 3. FRAMEWORK-AGNOSTIC WRAPPER (the lock-in prevention)
class LLMService:
```

```
    def __init__(self):
        self.client = OpenAI()

    def classify(self, text: str) -> str:
        r = self.client.chat.completions.create(
            model="gpt-4",
            messages=[{"role":"user","content":f"Classify: {text}. One word."}]
        )
        return r.choices[0].message.content.strip()

service = LLMService()
print("Wrapped:", service.classify("How much is Pro?"))
# To switch from OpenAI to Anthropic: change LLMService internals only
```

📺 **OUTPUT**

```
Raw API: billing
LCEL: billing
Wrapped: billing

# All 3 produce same result.
# Raw: 3 lines, full control, no streaming/batch
# LCEL: more code but streaming/batch/fallback free
# Wrapped: switch providers by changing one class
# CHOOSE based on actual needs, not hype.
```

LIBRARIES

langchain	Chains, LCEL, tools	`pip install langchain langchain-openai`
llama-index	RAG indexes, query engines	`pip install llama-index`
langgraph	Agent state machines	`pip install langgraph`
semantic-kernel	Microsoft orchestration	`pip install semantic-kernel`
haystack-ai	Pipeline NLP/GenAI	`pip install haystack-ai`
langsmith	Tracing/debugging	`pip install langsmith`

— POCKET NOTES —

1. LCEL + Chains + Runnables + Callbacks

```
LCEL = pipe operator: prompt | llm | parser
Analogy: LEGO bricks snapped together / Unix command pipes
Runnable: every component gets .invoke, .batch, .stream, .ainvoke FREE
RunnableParallel: run independent steps simultaneously (faster)
Fallbacks: chain.with_fallbacks([backup]) -- auto-switch provider
Retry: chain.with_retry(stop_after_attempt=2)
Callbacks: LangSmith for step-by-step tracing
Old Chain classes: DEPRECATED. Only use LCEL.
LangSmith: 2 env vars to enable. Essential for debugging.
pip install langchain langchain-openai
```

2. Connectors + Index Types + Query Engines + Routers

```
LlamaIndex = RAG-specialized framework. Like a bakery kitchen for bread.
Data connectors: 150+ via LlamaHub (PDF, Notion, Slack, DBs)
Index types:
  VectorStoreIndex: by meaning (DEFAULT)
  SummaryIndex: overview/summarization
  KeywordTableIndex: exact term lookup
  TreeIndex: hierarchical for large collections
  KnowledgeGraphIndex: entity connections
Query engine: index.as_query_engine(top_k=5)
Router: auto-route queries to best index type
SubQuestionQueryEngine: splits complex Qs automatically
800 lines LangChain RAG = 50 lines LlamaIndex
pip install llama-index
```

3. State Machines + Conditional Edges + Persistence + HITL

```
LangGraph = flowchart you can run. PRODUCTION STANDARD for agents.
Nodes: functions (boxes) | Edges: connections (arrows) | State: shared clipboard
Conditional edges: route based on state (if billing -> billing handler)
Cycles: loops (try -> fail -> retry)
Checkpointing: save progress. Resume after crash. SQLite(dev) / Postgres(prod).
Human-in-the-loop: interrupt_before=['node']. Pause for approval.
Streaming: graph.stream() shows progress per node.
Subgraphs: small flowcharts inside bigger flowcharts.
LangGraph Studio: visual step-by-step debugger.
pip install langgraph
```

4. Plugins + Planners + Azure Integration

```
Semantic Kernel = Microsoft's LLM orchestration SDK
Analogy: LangChain's cousin who grew up in the Microsoft neighborhood
```

```
Kernel: main brain | Plugins: tools | Planners: agent logic
Multi-language: Python + C# + Java
Azure OpenAI: first-class native integration
Best for: Azure stack, C#/.NET teams, Microsoft enterprise
Not for: Python-first teams, agent-heavy apps
Ecosystem: 5-10x smaller than LangChain
pip install semantic-kernel
```

5. Pipelines + Components + Document Stores

```
Haystack = pipeline-based NLP/GenAI framework (deepset, German)
Analogy: Lego Technic -- pieces only fit correctly, validated at build time
Components: generators, retrievers, embedders, converters
Pipelines: connect components as DAG. Type-checked at build time.
Document stores: InMemory, Qdrant, Elasticsearch, Weaviate
NLP heritage: NER, classification, not just LLM
Haystack 2.0: complete rewrite. Only use 2.x.
Best for: search apps, NLP+LLM hybrid, European enterprise
Smaller community but excellent docs
pip install haystack-ai
```

6. Decision Framework + Anti-Patterns

```
Raw API: simple apps, max control, learning. The grocery store walk.
LangChain: multi-step chains, streaming, batch. The car.
LangGraph: agents, routing, loops, persistence. The delivery truck.
LlamaIndex: RAG-focused, indexes, query routing. The library specialist.
Semantic Kernel: Azure, C#/.NET, Microsoft. The Microsoft office.
Haystack: type-safe, NLP+LLM, European. German engineering.

5 ANTI-PATTERNS:
  Framework first (prototype with raw calls first)
  Over-abstraction (simpler without? skip it)
  Lock-in (wrap framework calls in YOUR interfaces)
  Version chasing (pin versions, test upgrades)
  Multiple frameworks (pick ONE primary)

Rule: add framework only when you feel the pain it solves
```

— INTERVIEW PREP —

1. LCEL + Chains + Runnables + Callbacks

```
SAY THIS: 'I build all LLM pipelines with LCEL. Every component is a Runnable with invoke, batch, stream, and async support out of the box. I use RunnableParallel for concurrent steps, fallbacks for reliability, and LangSmith for production observability.'

Q: When is LangChain overkill?
A: 'For simple single-call apps -- a basic chatbot or Q&A. Raw API calls are simpler for those. LangChain adds value when you have multi-step chains, tool use, streaming, or need batch/retry/fallback from the same code.'

Q: LCEL vs legacy chains?
A: 'Legacy chains are deprecated. LCEL is the only path. It is more composable, streams natively, and has better error handling. Any tutorial using LLMChain is outdated.'
```

2. Connectors + Index Types + Query Engines + Routers

```
SAY THIS: 'I use LlamaIndex for RAG-focused applications. It abstracts the entire pipeline -- loading, indexing, retrieval, synthesis -- in a fraction of the code. The RouterQueryEngine automatically directs queries to the best index type.'

Q: LlamaIndex vs LangChain for RAG?
A: 'LlamaIndex has purpose-built abstractions: multiple index types, built-in parent-child retrieval, automatic query routing. LangChain can do RAG but needs more manual wiring. For pure RAG: LlamaIndex. For agents + RAG: LangGraph + LlamaIndex.'
```

Q: When would you NOT use LlamaIndex?
A: 'Agent-heavy apps with complex tool use and state management -- LangGraph is better. Simple single-API-call apps -- raw calls are simpler. When you need fine-grained control over every step -- LlamaIndex abstractions can be opaque.'

3. State Machines + Conditional Edges + Persistence + HITL

SAY THIS: 'LangGraph is my production framework for agents. It models the agent as a state machine graph with conditional routing, built-in persistence, and human-in-the-loop. I use TypedDict for state, checkpoint to PostgreSQL, and compose complex flows from smaller subgraphs.'

Q: LangGraph vs LCEL chains?
A: 'LCEL for linear pipelines (A->B->C). LangGraph for anything with branching, loops, or state management. In practice, most production agents need LangGraph because they need at least one conditional route.'

Q: How do you test LangGraph agents?
A: 'Unit test individual nodes. Integration test the full graph with mock tools. LangGraph Studio for visual debugging. LangSmith for production tracing.'

4. Plugins + Planners + Azure Integration

SAY THIS: 'I evaluate Semantic Kernel for Microsoft-heavy environments. Its multi-language support and native Azure integration make it strong for enterprise .NET shops. For Python-first teams, LangChain has a larger ecosystem.'

Q: SK vs LangChain?
A: 'SK if: Azure stack, C# team, Microsoft enterprise. LangChain if: Python-first, larger community, more integrations, more mature agents.'

Q: Is SK production-ready?
A: 'Yes for Azure enterprise apps. Microsoft uses it internally. But the community is smaller, so finding solutions to edge cases takes longer.'

5. Pipelines + Components + Document Stores

SAY THIS: 'I consider Haystack for search-heavy and NLP+LLM hybrid apps. Its strongly typed pipeline validation catches integration errors at build time. The component abstraction is cleaner than LangChain for retrieval pipelines.'

Q: Haystack vs LangChain?
A: 'Haystack if: search-focused, need type-safe pipelines, NLP+LLM hybrid, European enterprise. LangChain if: agent-focused, need largest ecosystem, maximum third-party integrations.'

Q: Is Haystack production-ready?
A: 'Yes, especially for RAG and search. deepset offers managed deployment. Community is smaller but docs are excellent.'

6. Decision Framework + Anti-Patterns

SAY THIS: 'I follow minimal abstraction. I start with raw API calls and add framework layers only when I feel specific pain -- composability, streaming, state management. My stack: LangGraph for agents, LlamaIndex for RAG, LCEL for multi-step chains. I keep business logic framework-agnostic to avoid lock-in.'

Q: Your team wants LangChain for everything. Pushback?
A: 'LangChain adds value for multi-step chains and streaming. For simple API calls, it adds complexity without benefit. Guidelines: raw calls for single-step, LCEL for multi-step, LangGraph for agents. Pin versions -- LangChain APIs change often.'

Q: How to avoid framework lock-in?
A: 'Wrap framework calls in my own interfaces. My LLMService class calls LangChain internally but exposes a clean interface. Switch to LlamaIndex = change the wrapper, not 200 call sites. Dependency inversion for AI frameworks.'
